The cause of failure is often either overtopping or piping. The modeling of dam breaching due to either or both of these causes is of fundamental importance to development of dam-safety programs. This book is, therefore, an attempt to present some aspects of earth-dam breach modeling technology.

Before dam breach models are applied as prediction tools, no matter what type of model, they are often calibrated to a data set. Historical dam breach data are therefore used to feed the models, but data on real-life embankment failures are usually poorly documented for various reasons (ASCE/EWRI, 2011).Uncertainties on breach properties, such as average breach width and failure time, have ...

Modeling a Dam Breach. HydroCAD-10 provides a new "outlet device" for modeling a progressive dam breach. The breach can begin at any desired time or water surface elevation, and develop over a user-specified interval. A dam breach is modeled as flow through a trapezoidal weir in which the weir rise (height) increases linearly over time.

Dam failures are inevitable. Despite technological progress in dam engineering, dams continue to fail. For example, the period 1946 to 1955 has on record 12 major failures and 2000 new dams constructed, while the period 1956 to 1965 records 24 failures and 2500 new dams (Johnson and Illes, 1976).

Dam break hydraulics are highly transient (exhibiting high velocity and water level gradients that can change dramatically in time and space). Dam break modelling completed using TUFLOW Classic typically requires the double precision version of TUFLOW and smaller timesteps than what is considered 'normal' for catchment flood modelling because of the transient nature of dam break flows.
